October 21, 2020

# Discrepancy Notation

## Definition (Local Discrepancy)

If  $\mathcal{S}$  is a class of sets in  $[0, 1]^d$ , then for  $S \in \mathcal{S}$ , the local discrepancy of a point set  $P \subseteq [0, 1]^d$  with respect to  $S$ , with  $|P| = n$ , is

$$D(P, S) = |S| - n^{-1}|P \cap S|$$

(Note that this is the “normalized” version of discrepancy).

This talk will focus on discrepancy with respect to the set  $\mathcal{C}$  of corners (boxes anchored at the origin) in the unit cube  $[0, 1]^d$ . We define a corner  $C_x \in \mathcal{C}$  in terms of its largest point  $\mathbf{x} = (x_1, \dots, x_d)$ :

$$C_x = \{y \in [0, 1]^d : 0 \leq y_i < x_i \text{ for } i = 1, \dots, d\}$$

# Discrepancy Notation

Definition (Star-Discrepancy with respect to  $\mathcal{S}$ )

$$D_{\infty}^*(P, \mathcal{S}) = \sup_{S \in \mathcal{S}} |D(P, S)|$$

Definition (Minimal Star-Discrepancy with respect to  $\mathcal{S}$  of an  $n$ -point subset in  $[0, 1)^d$ )

$$D_{\infty}^*(n, d) = \inf\{D_{\infty}^*(P, \mathcal{S}) : P \subset I^d, |P| = n\}$$

Discrepancy results can also be stated in terms of the ‘inverse discrepancy,’ which gives the minimum number of points with discrepancy at most  $\epsilon$ .

Definition (Inverse Discrepancy)

$$N_{\infty}^*(d, \epsilon) = \min\{n : D_{\infty}^*(n, d) \leq \epsilon\} = \min\{|P| : P \subset I^d, D_{\infty}^*(P) \leq \epsilon\}$$

# Search for Bounds Based on Dimension

- The asymptotic behavior of  $D_{\infty}^*(P, \mathcal{C}_d)$  (where  $\mathcal{C}$  is the class of corners in  $[0, 1]^d$ ) is of order at most  $n^{-1} \log(n)^{d-1}$ : points which achieve this are called low-discrepancy points
- For some applications, the dimension  $d$  may be huge
- Then the usual discrepancy bounds are of no help as  $n^{-1} \log(n)^{d-1}$  is increasing for  $n \leq \exp(d - 1)$ : in practice,  $\exp(d - 1)$  is prohibitively large

# Vapnik-Cervonenkis Classes

## Definition (VC Class)

A countable family  $\mathcal{F}$  of measurable subsets of  $X$  is a VC-class if there is a nonnegative integer  $\nu$  such that

$$|\{A \cap F : F \in \mathcal{F}\}| < 2^{\nu+1}$$

for any point subset  $A \subset X$  with  $|A| = \nu + 1$ . The smallest such  $\nu$  is called the **VC-dimension** of  $\mathcal{F}$ .

In other words,  $\mathcal{F}$  is a VC-class if there is some integer  $\nu$  such that any subset of cardinality  $\nu + 1$  cannot be “shattered” by sets in  $\mathcal{F}$ .

## Definition (Shattering)

$\mathcal{F}$  is said to **shatter** a point set  $A$ ,  $|A| = n$ , if

$$|\{A \cap F : F \in \mathcal{F}\}| = 2^n$$

# Examples of the VC Dimension

Class of Sets	VC Dimension	
Semi-Infinite Intervals in $\mathbb{R}$	1	
Closed Intervals in $\mathbb{R}$	2	
Corners in $\mathbb{R}^d$	$d$	

# Examples of the VC Dimension

Class of Sets	VC Dimension	
Closed Halfspaces in $\mathbb{R}^d$	$d + 1$	
Axis-Parallel Boxes in $\mathbb{R}^d$	$2d$	
Disks in $\mathbb{R}^2$	3	
Balls in $\mathbb{R}^d$	$d + 1$	
Convex Sets in $\mathbb{R}^d$	$\infty$	

# Important Inequality for VC Classes

## Lemma (Sauer-Shelah Lemma)

$$|\{A \cap F : F \in \mathcal{F}\}| \leq \sum_{i=0}^v \binom{|A|}{i} = O(|A|^v)$$

(In other words: if the VC-dimension of  $\mathcal{F}$  is  $v$ , then  $\mathcal{F}$  can consist of at most  $O(|A|^v)$  sets).

**Proof:** Induction on  $n+v$  (where  $|A| = n$ )

# Covering Numbers

## Definition (Covering Number)

The covering number  $\mathcal{N}(M, d, \epsilon)$  of a metric space  $(M, d)$  is the smallest number of closed  $\epsilon$ -balls

$$B(x, \epsilon) := \{y \in M : d(x, y) \leq \epsilon\}$$

that cover  $M$ . If there is no finite cover we set  $\mathcal{N}(M, d, \epsilon) = \infty$ .

There are nice connections between covering/packing numbers and VC-classes.

# Covering Numbers: $\ell^2$ Distance

# Covering Numbers: Symmetric Difference of Corners

# VC-Classes and Discrepancy

The proofs we will discuss are heavily dependent on the fact that the set of corners in  $[0, 1]^d$  is a VC-class of dimension  $d$ . Some important features that make VC-classes interesting/natural to study in discrepancy theory:

- Low complexity
- As discussed above, known geometric properties (i.e. connections with covering numbers)
- Direct implications for combinatorial discrepancy

# Upper Bounds for Discrepancy Based on Dimension

Theorem (Heinrich, Novak, Wasilkowski, Wozniakowski, '01, Thm 1)

For all  $n, d \in \mathbb{N}$ ,

$$D_{\infty}^*(n, d) \leq 2\sqrt{2}n^{-1/2} \left( d \log \left( \lceil \frac{dn^{1/2}}{(2 \log 2)^{1/2}} \rceil + 1 \right) + \log 2 \right)^{1/2}$$

Theorem (Heinrich, Novak, Wasilkowski, Wozniakowski, '01, Thm 3)

There is a positive number  $c$  such that for all  $n, d \in \mathbb{N}$ ,

$$D_{\infty}^*(n, d) \leq cd^{1/2}n^{-1/2} \text{ (and } n_{\infty}^*(d, \epsilon) \leq \lceil c^2 d \epsilon^{-2} \rceil \text{)}.$$

Theorem 1 above can be proven using basic features of empirical process theory, while the proof of Theorem 3 requires deeper results that make use of the fact that the class of corners  $\mathcal{C}$  is a VC-class of dimension  $d$ .

# Hoeffding's Inequality vs. Bernstein's Inequality

For  $X_1, \dots, X_n$  i.i.d random,  $\mathbb{E}[X_i] = 0$ ,  $|X_i| \leq 1$  for each  $i$ , we have

## Hoeffding's Inequality

$$\mathbb{P}\left(\left|\sum_{i=1}^n X_i\right| \geq t\right) \leq \exp(-2t^2/n)$$

## Bernstein's Inequality

$$\mathbb{P}\left(\left|\sum_{i=1}^n X_i\right| \geq t\right) \leq 2 \exp\left(-\frac{t^2/2}{\sum_{i=1}^n \mathbb{E}[X_i^2] + t/3}\right)$$

Thus, Bernstein's inequality gives good bounds for random variables with low variance.

## Proof of Theorem 1 (weak upper bound)

- Take  $\delta > 0$  and replace set of corners with a finite set  $\Gamma_m$ , the equidistant grid on  $[0, 1]^d$  with mesh-size  $1/m$ , where  $m = \lceil d/\delta \rceil$
- Then, we can show that the supremum in the definition of  $\star$ -discrepancy can be replaced with the maximum over the finite set  $\Gamma_m$  with a possible decrease of the  $\star$ -discrepancy by  $\delta$ :

$$D_{\infty}^*(\mathbf{p}_1, \dots, \mathbf{p}_n) \leq \max_{\mathbf{x} \in \Gamma_m} \left| x_1 \cdots x_d - \frac{1}{n} \sum_{i=1}^n \mathbf{1}_{C_{\mathbf{x}}}(\mathbf{p}_i) \right| + \delta$$

## Proof of Theorem 1 (weak upper bound)

- Let  $\tau_1, \dots, \tau_n$  be iid uniform random variables and take

$$\xi_{\mathbf{x}}^{(i)} = x_1 \cdots x_d - 1_{[0, \mathbf{x})}(\tau_i), \quad i = 1, \dots, n$$

- Obtain, via Hoeffding:  $\mathbb{P}\left(\left|n^{-1} \sum_{i=1}^n \xi_{\mathbf{x}}^{(i)}\right| \geq \delta\right) \leq 2 \exp(-\delta^2 n/2)$
- Then  $\mathbb{P}(D_{\infty}^*(\tau_1, \dots, \tau_n) \leq 2\delta) \geq \mathbb{P}(\max_{\mathbf{x} \in \Gamma_m} \left|n^{-1} \sum_{i=1}^n \xi_{\mathbf{x}}^{(i)}\right| \leq \delta)$   
 $= 1 - \mathbb{P}(\max_{\mathbf{x} \in \Gamma_m} \left|n^{-1} \sum_{i=1}^n \xi_{\mathbf{x}}^{(i)}\right| > \delta) \geq 1 - 2(m+1)^d \exp(-\delta^2 n/2)$
- This is strictly positive for  $\delta > \delta_0$ , where

$$\delta_0^2 = 2n^{-1} \left( d \log \left[ \frac{dn^{1/2}}{2(\log 2)^{1/2}} + 1 \right] + \log 2 \right)$$

- Hence, for any  $\delta > \delta_0$  there are points  $\tau_1, \dots, \tau_n$  such that  $D_{\infty}^*(\tau_1, \dots, \tau_n) \leq 2\delta$ . Thus  $D_{\infty}^*(n, d) \leq 2\delta_0$  and the proof is complete

## Sketch of Proof of Theorem 3 (strong upper bound)

To obtain the stronger upper bound  $D_{\infty}^*(n, d) \leq cd^{1/2}n^{-1/2}$ , we use that the set of corners in  $[0, 1]^d$  is a VC-class of dimension  $d$ . Central to the proof is the following VC-type inequality from Talagrand (combined with a result of Haussler on covering numbers), from which the discrepancy bound follows fairly easily.

### Theorem (Heinrich, Novak, Wasilkowski, Wozniakowski, '01, Thm 2)

*There is a positive number  $K$  such that for each countable VC-class  $\mathcal{F}$  (subsets of  $X$ ) and for each probability measure  $P$  on  $X$ , the following holds: For all  $s \geq Kv(\mathcal{F})^{1/2}$  and all natural  $n$ ,*

$$\mathbb{P}\left(\omega : \sup_{F \in \mathcal{F}} \left| P(F) - \frac{1}{n} \sum_{i=1}^n 1_F(X_i(\omega)) \right| \geq sn^{-1/2} \right) \leq \frac{1}{s} \left( \frac{Ks^2}{v(\mathcal{F})} \right)^{v(\mathcal{F})} e^{-2s^2}$$

*where  $v(\mathcal{F})$  is the VC-dimension of  $\mathcal{F}$ .*

## Sketch of Proof of Theorem 3 (strong upper bound)

$$\mathbb{P}\left(\omega : \sup_{F \in \mathcal{F}} \left| P(F) - \frac{1}{n} \sum_{i=1}^n 1_F(X_i(\omega)) \right| \geq sn^{-1/2} \right) \leq \frac{1}{s} \left( \frac{Ks^2}{v(\mathcal{F})} \right)^{v(\mathcal{F})} e^{-2s^2}$$

First we show how the discrepancy bound follows from this VC-type inequality:

- Approximate the set of corners  $\mathcal{C}$  by

$$\mathcal{C}_{\mathbb{Q}} = \{[0, \mathbf{x}] : \mathbf{x} = (x_1, \dots, x_d) \in ([0, 1] \cap \mathbb{Q})^d\}$$

- Take  $s = \lambda v(\mathcal{C}_{\mathbb{Q}})^{1/2}$ , choose  $\lambda_0$  so that  $K\lambda^2 \leq e^{2\lambda^2}$  for all  $\lambda \geq \lambda_0$ .
- Then for  $\lambda > \max(K, \lambda_0, 1)$ , the RHS of the VC-inequality above is strictly smaller than 1
- This ensures the existence of a point set  $P$  with star-discrepancy less than  $cd^{1/2}n^{-1/2}$ , where  $c$  is some positive number.

# Sketch of Proof of Talagrand's VC Inequality

**Desired Result:** For a class of sets  $\mathcal{F}$  and i.i.d random variables such that there exists a  $V > 0$  with  $X_1, \dots, X_n$  satisfying  $\mathcal{N}(\mathcal{F}, d_P, \epsilon) \leq \left(\frac{V}{\epsilon}\right)^V$  where  $d_P(C_1, C_2) = P(C_1 \Delta C_2)$ ,

$$\mathbb{P}\left(\omega : \sup_{F \in \mathcal{F}} \left| P(F) - \frac{1}{n} \sum_{i=1}^n 1_F(X_i(\omega)) \right| \geq sn^{-1/2} \right) \leq \frac{1}{s} \left( \frac{Ks^2}{V(\mathcal{F})} \right)^{V(\mathcal{F})} e^{-2s^2}$$

**Note:** The covering number condition for VC classes, as used in the proof of the upper bound for discrepancy with respect to corners, is a result of Haussler (1995).

# Sketch of Proof of Talagrand's VC Inequality

Idea: first study **Gaussian processes**  $(X_t)_{t \in T}$  for which  $N(T, d, \epsilon) \leq (A/\epsilon)^\nu$  for some constants  $A, \nu$  and  $0 < \epsilon < \sigma = (\sup_{t \in T} \mathbb{E}[X_t^2])^{1/2}$

- Obtain bounds on tails of supremum by breaking index set into suitable pieces
- Partitioning the index set  $T$  into  $N$  pieces each of diameter  $\leq a \leq \sigma$ , we can obtain a bound on  $\mathbb{P}(\sup_{t \in T} X_t \geq u)$  that depends on  $\mathbb{E}[\sup_{t \in T} X_t]$ .
- We need to control both  $N$ , the number of pieces, and the expectation.
- Instead of the crude partition, take an (essentially) dyadic partition: the union of sets  $\mathcal{P}_l$ , for  $p \leq l \leq q$ , such that each set in  $\mathcal{P}_l$  has diameter  $\leq 4^{-l+1}$ .

# Sketch of Proof of Talagrand's VC Inequality

For the **general (non-Gaussian) case**:

- Use same partitioning scheme
- Bound on  $\mathbb{P}\left(\sup_{t \in \mathcal{T}} X_t \geq u\right)$  looks slightly different (a bit more complicated) in non-Gaussian case, but still requires controlling  $\mathbb{E}[\sup_{t \in \mathcal{T}} X_t]$
- For indices whose corresponding random variables have small variance, it is easy (via Bernstein's inequality) to control the tails and get a good bound on  $\mathbb{E}[\sup_{t \in \mathcal{T}} X_t]$ .
- Then, bound the cardinality on the set of remaining random variables (with large variance): its contribution is controlled.

# Aistleitner's Improvement with Dyadic Partitioning

## Theorem (Aistleitner, 2011)

$$D_{\infty}^*(n, d) \leq 9.65d^{1/2}n^{-1/2}$$

- Approximate with a finite set – roughly  $N^{d/2}$  sampling points are needed, as in the previously known proofs
- Use direct dyadic partitioning argument rather than “black-box” of VC-inequality
- Express the indicator function  $1_{C_x}$  as a sum of indicator functions for a few sets with large variance and many with small variance. Use Bernstein's inequality (rather than Hoeffding) on the many variables with small variance leads to an improvement in the bound.

# Sketch of Aistleitner's Proof

Use Gnewuch's bounds on covering and bracketing numbers.

(**Bracketing** is a more restricted notion of covering: a finite set  $\Delta$  of pairs of points of  $[0, 1]^d$  is an  $\epsilon$ -bracketing cover if for every pair  $(x, z) \in \Delta$ , the estimate  $\lambda(C_z) - \lambda(C_x) \leq \epsilon$  holds, and for every  $y \in [0, 1]^d$ , there is a pair  $(x, z)$  such that  $x \leq y \leq z$ .)

Gnewuch bounds:

$$\mathcal{N}([0, 1]^d, \lambda, \epsilon) \leq (2e)^d (\epsilon^{-1} + 1)^d$$
$$\mathcal{N}_{[]}([0, 1]^d, \lambda, \epsilon) \leq 2^{d-1} e^d (\epsilon^{-1} + 1)^d$$

# Sketch of Aistleitner's Proof

- $d=1$  and  $d=2$ : theorem is clear (known examples), so assume  $d \geq 3$
- Let  $K = \lceil (\log_2 n - \log_2 d)/2 \rceil$ .
- For  $1 \leq k \leq K - 1$ , let  $\Gamma_k$  be a  $2^{-k}$  cover for which  $|\Gamma_k|$  satisfies Gnewuch covering bound
- Let  $\Gamma_K$  be a  $2^{-K}$  bracketing cover for which  $|\Gamma_K|$  satisfies Gnewuch bracketing bound

Fix  $x \in [0, 1]^d$ , pick the pair  $(v_K, w_K) = (v_K(x), w_K(x))$  in the **bracketing cover** for which  $v_K \leq x \leq w_K$ . Then define

$$p_K(x) = v_K(x)$$

$$p_{K-1}(x) = v_{K-1}(p_K(x))$$

$$p_{K-2}(x) = v_{K-2}(p_{K-1}(x))$$

$\vdots$

$$p_1(x) = v_1(p_2(x))$$

Suppose  $K = 4$ .

where, in the above,  $v_k(x) \in \Gamma_k$  for  $1 \leq k \leq K - 1$

# Sketch of Aistleitner's Proof

## Sketch of Aistleitner's Proof

- For  $0 \leq k \leq K - 1$ , if  $A_k$  is the set of all sets of the form  $C_{p_{k+1}(x)} \setminus C_{p_k(x)}$ ,  $A_k$  has at most  $|\Gamma_{k+1}| \leq (2e)^d (2^{k+1} + 1)^d$  elements.
- If  $A_K$  is the set of all sets of the form  $C_{w_K(x)} \setminus C_{p_K(x)}$ ,  $A_K$  has at most  $|\Gamma_K| \leq 2^{d-1} e^d (2^K + 1)^d$  elements.

Let  $X_1, \dots, X_n$  be i.i.d. uniformly distributed random variables on  $[0, 1]^d$ .

Use Bernstein's inequality to bound, for  $I$  in  $A_k$  with  $k \geq 2$

$$\mathbb{P}\left(\left|\frac{1}{n} \sum_{j=1}^n \mathbf{1}_I(X_j) - \lambda(I)\right| > t\right)$$

(for  $k = 0, 1$ , the intervals are larger, and Hoeffding's inequality gives a better bound)

## Sketch of Aistleitner's Proof

Then...

- Writing  $B_k = \bigcup_{I \in A_k} \left( \left| \frac{1}{n} \sum_{j=1}^n \mathbf{1}_I(X_j) - \lambda(I) \right| > c_k \sqrt{d/n} \right)$
- Choose constants  $c_k$  appropriately so that  $\mathbb{P}(B_0), \mathbb{P}(B_1), \mathbb{P}(B_2) \leq \frac{1}{4}$ , and  $\mathbb{P}(B_k) \leq 2^{-k}$  for higher  $k$ . Then

$$\sum_{k=0}^K \mathbb{P}(B_k) \leq \frac{3}{4} + \sum_{k=3}^K 2^{-k} < 1$$

- This ensures the existence of a realization  $X_1(\omega), \dots, X_n(\omega)$ , such that  $\omega \notin \bigcup_{k=0}^K B_k$
- Then for any  $x \in [0, 1]^d$ , use the estimates (with constants) from the finite partition to find  $c$  such that

$$\mathbb{P} \left( \left| \frac{1}{n} \sum_{j=1}^n \mathbf{1}_{C_x}(X_j(\omega)) - x \right| > c \sqrt{d/n} \right)$$

- In the end,  $c \approx 9.65$ .

## Improvements on Constant

A number of improvements have been made on the constant in the previous proof:

- $c \approx 9$ : Pasing and Weiss 2018 – uses Aistleitner's method combined with an improvement on the bound for bracketing covers

$$\mathcal{N}_{[]}^{\square}(d, \epsilon) \leq 2^{d-2} e^d (\epsilon^{-1} + 1)^d + \frac{1}{2} (\epsilon^{-1} + 1)$$

- $c \approx 2.7868$ : Doerr 2016
- $c \approx 2.5287$ : Gnewuch and Hebbinghaus 2019
- $c \approx 2.4968$ : Pasing and Weiss 2020 – again, Aistleitner's method combined with a new improvement on the bound for bracketing covers

$$\mathcal{N}_{[]}^{\square}(d, \epsilon) \leq \max(1.1^{d-101}, 1) \frac{d^d}{d!} (\epsilon^{-1} + 1)^d$$

## Lower Bound

Hinrichs built upon the ideas in HNWW by using the VC-property of the class of corners to improve the lower bound on the star-discrepancy that is polynomial in  $d/n$  (like the upper bound).

### Theorem (Hinrichs, 2003, Thm 1)

*There exist constants  $c, \epsilon_0 > 0$  such that*

$$D_{\infty}^*(n, d) \geq \min(\epsilon_0, cd/n)$$

There is also a theorem of Doerr regarding the lower bound for the expected discrepancy of a random point set:

### Theorem (Doerr, 2014, Thm 1)

*There is constant  $k$  such that if  $d \leq n$  and  $P$  is an  $n$ -point subset chosen independently and uniformly at random from  $[0, 1]^d$ ,*

$$\mathbb{E}[D_{\infty}^*(P, \mathcal{C}_d)] \geq K\sqrt{d/n}.$$

# Lower Bound

## Theorem (Hinrichs, 2003, Thm 4)

Let  $\mathcal{F}$  be a VC-class of dimension  $v$  which is closed under intersections and let  $\mathbb{P}$  be a probability measure. Assume that there exists a constant  $\kappa > 0$  such that  $N(\mathcal{F}, d_{\mathbb{P}}, \epsilon) \geq (\kappa\epsilon)^{-v}$  for all  $\epsilon > 0$ . Then there exist constants  $c, \epsilon_0 > 0$  such that for all  $n$  and all  $P \subset X$  with  $|P| = n$ ,

$$D_{\infty}^*(P) \geq \min(\epsilon_0, cv/n).$$

Above,  $d_{\mathbb{P}} = \mathbb{P}(C_1 \Delta C_2)$ .

The proof of this theorem makes use of the Sauer-Shelah Lemma. As the set of corners is a VC class, Theorem 4 implies Theorem 2 once it is shown there is some  $\kappa > 0$  such that  $N(\mathcal{C}, d_{\mathbb{P}}, \epsilon) \geq (\kappa\epsilon)^{-d}$  for all  $\epsilon > 0$ .

# Open Problems

- Upper bound:  $D_{\infty}^*(n, d) \lesssim (d/n)^{1/2}$

Lower bound:  $D_{\infty}^*(n, d) \gtrsim d/n$

Close the gap!

- Find points that satisfy the stronger upper bound **constructively** – this is more useful for problems involving high-dimensional integration with Quasi-Monte Carlo methods
